- 5 thereto.

1 STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR
2 DEVELOPMENT (Not applicable.)

3

4

BACKGROUND OF THE INVENTION

5 The present invention relates to novel hybrid coated cosmetics powders and methods
6 of making and using same. More particularly, the invention relates to novel
7 compositions and methods for coating insoluble cosmetics powders, for example
8 inorganic and organic, pigments and fillers, to the coated powders produced, to
9 cosmetic and other formulations incorporating such coated powders and to methods
10 of making and using said coated powders and formulations. Preferred embodiments
11 of the invention include novel coated cosmetic powders having a unique combination
12 of excellent hydrophobic and lipophilic properties which is particularly advantageous
13 in many cosmetic applications.

14

15 Most cosmetics formulations include in their compositions cosmetic powders, finely
16 divided particles of solid, insoluble materials, for example pigments and fillers, that
17 can serve a variety of functions, such as providing desired visual properties such as
18 opacity and color, desired tactile properties such as viscosity and feel, special effects
19 such as pearlescence and iridescence and various other desirable properties, for
20 example oil absorbency. Cosmetic powders include inorganic materials such as metal
21 oxides, silicates and carbonates as well as organic pigments or lakes such as
22 ultramarine and crimson lake and polymeric particulates such as nylon and cellulose.
23 Additional examples of pigments that can be employed in the present invention are
24 set forth hereinbelow. Some examples of cosmetic formulations employing powders
25 include liquid or powder makeups and foundations, moisturizing and antiaging
26 creams and lotions, nail polish, lipstick, mascara and eye shadow, to name but a few.

27

28 Primarily because of their surface characteristics, it may be difficult to satisfactorily
29 incorporate raw, untreated powders into liquid or powdered cosmetic bases or

1 excipients in a manner providing uniform stable dispersions. Desirably, the powders
2 should be uniformly distributed throughout the base or excipient medium and the
3 dispersion should remain stable over time with no significant settling or
4 agglomeration occurring before the product is eventually used by the end consumer,
5 which can be as much as two or more years after manufacture. It is also desirable that
6 the powders should not impart unaesthetic characteristics to the end- product
7 cosmetic formulation, such as a gritty or sandy feel, which may result from
8 agglomeration of powder particles or the presence of oversized particles in the
9 pigment powder, discoloration attributable to non-uniform distribution of the powder,
10 and other negative characteristics such as settling.

11

12 Many pigment materials for example metal oxides and carbonates, have a somewhat
13 hydrophilic surface, or bear hydrophilic moieties or ions on their external surfaces
14 which render the powder particles prone to agglomerate in aqueous media which are
15 commonly employed in cosmetics.

16

17 Accordingly, over the years, many compositions and methods have been employed
18 and proposed for treating or coating insoluble cosmetic powders, in order to overcome
19 these and other problems. Such prior proposals have met with considerable success
20 and it is now standard practice in the cosmetics industry to coat powders for cosmetic
21 use. In particular, it is well known to "hydrophobize" cosmetic powders, which is to
22 say to treat the powders to render them more hydrophobic, thus providing more
23 stable dispersions (or suspensions) in aqueous media.

24

25 Powders can be hydrophobized by treatment with a suitable coating agent in a liquid
26 medium, for example by mixing or spraying the coating agent with or on to the
27 powder and heating the mixture, optionally under vacuum to remove volatile
28 solvents, if employed. Preferred coating agents are chemically reactive with the
29 substrate powder to provide a durable covalent bond thereto and have hydrophobic

1 chemical backbones or substituents that can provide a hydrophobic outer layer, skin
2 or shell around each individual powder particle. The coating agent may react, for
3 example, with hydroxyl groups, oxide ions, available oxygen atoms or other suitable
4 reactive groups normally present on the surface of the cosmetic powder being coated.

5
6 Mitchell Schlossman US Patent No. 4,877,604 ("Schlossman '604" hereinafter), the
7 disclosure of which is herein incorporated by reference thereto, discloses and claims
8 the use of organotitanates, to coat pigments and other cosmetic powders, one
9 preferred coating agent being isopropyl titanium triisostearate. Schlossman '604
10 discloses that the claimed coating materials and methods can provide uniform and
11 stable dispersions of pigments and other cosmetic materials, such as talc, sericites and
12 mica. Such dispersion uniformity can avoid the need to colloid mill the final emulsion
13 to achieve smoothness and homogeneity in various cosmetic products, for example, in
14 oil-in-water liquid makeups, avoiding settling or segregating out of pigments or other
15 cosmetic material thereby increasing the shelf-life of the product. In addition, the use
16 of Schlossman '604's titanate-treated pigments in liquid pigment and/or color
17 extenders can improve the viscosity range providing more uniform extenders and
18 enabling extenders to be utilized without adversely affecting the viscosity of the final
19 product.

20
21 Other advantages to using treated or coated materials in accordance with Schlossman
22 '604 include increased water resistance due to hydrophobic characteristics, reduced
23 need for powder blends, increased smoothness on application of anhydrous and
24 powder blends, better skin adhesion, better appearance of frosted products, less
25 streaking in pressed and anhydrous makeup products and noticeable smoothness and
26 ease of manufacture of compact cream makeup.

27
28 Thus, the Schlossman '604 organometallate coating materials provide an array of
29 attractive features. Pursuant to the insights of the invention, it would be desirable to

1 provide coatings for cosmetic powders which retain these benefits and which can
2 extend potential uses of the resultant coated powders to environments where
3 isopropyl titanium triisostearate treated pigment may not always be satisfactory, for
4 example in silicone fluids and in low pH media. The latter are often required for skin
5 care products containing alpha-hydroxy acids.

6
7 It is also known to employ functionalized silanes, including for example, triethoxy
8 octylsilane to provide a silicone coating on cosmetic powders to render them
9 hydrophobic. With regard to terminology, it is notable that even extensively
10 substituted derivatives of silane, such as triethoxy decyl silane are sometimes
11 generally referenced in the art by the catch-all phrase "silanes". While silane- coated
12 powders may display good hydrophobicity they may not be adequately lipophilic for
13 some purposes yielding unacceptably viscous dispersions in cosmetic oils such as
14 mineral oil. A further problem is that silicone coated pigments may display color
15 shift over time. Hollenberg et al. United States Patent No. 5,143,722 is but one
16 example of a disclosure of silane coated cosmetic pigments providing silicone coated
17 pigment powders.

18
19 The foregoing description of background art may include insights, discoveries,
20 understandings or disclosures, or associations together of disclosures, that were not
21 known to the relevant art prior to the present invention but which were provided by
22 the invention. Some such contributions of the invention may have been specifically
23 pointed out herein, whereas other such contributions of the invention will be apparent
24 from their context. Merely because a document may have been cited here, no
25 admission is made that the field of the document, which may be quite different from
26 that of the invention, is analogous to the field or fields of the invention.

27
28 BRIEF SUMMARY OF THE INVENTION

1 The present invention solves the above mentioned problems of the related arts by
2 providing a process of coating any one or more of a wide range of cosmetic or other
3 powders with a novel hybrid coating agent comprising reacting a combination of a an
4 organotitanate or other suitable hydrophobizing organometallate and a functionalized
5 silicon compound with the powder or powders to produce hybrid coated powders.
6 The invention enables a wide range of powders to be effectively coated to have a
7 number of desirable properties such as good water repellency, good stability, a
8 smooth feel and good adhesion to the skin to be produced. The powders that may be
9 coated include common cosmetic powders such as metal oxide pigments and metal
10 carbonate, silicate or other fillers, as well as more exotic powders such as sericites and
11 metal oxide coated micas. Preferred hybrid coated powders of the invention display
12 all of these properties. The invention also provides novel processes for producing the
13 coated cosmetic powder and cosmetics made with the treated pigment or other
14 powder.

15

16 Preferably, both the organometallate and the functionalized silicon compound are
17 sufficiently reactive to covalently bond with the powder and each have chemical
18 structures providing hydrophobicity to the coated powder. In addition it is
19 particularly preferred that organometallate and the functionalized silicon compound
20 are capable of reacting with each other. Preferably also, the organometallate and
21 silicon compound are selected so as to avoid impeding each other's functionality.

22

23 The functionalized silicon compound can be any one, or a mixture, of a wide range of
24 compounds including a functionalized silane, a functionalized silicone, e.g. a
25 polysiloxane, or fluorinated analogs of the foregoing.

26

27 In one embodiment, the invention provides a cosmetic powder, for example a
28 pigment, extender pigment or filler, treated or coated with a hybrid coating agent
29 comprising an organic titanate and a trialkoxyalkylsilane. After reaction in the

1 processes of the invention, for example by heat treatment, these compounds become
2 chemically bonded to the surface of the pigments or fillers.

3

4 Coated pigment powders according to the invention may have both hydrophobic
5 and lipophilic properties or both hydrophobic and lipophobic properties. Use of
6 fluorinated silicon compounds can provide the lipophobic properties.

7

8 Some embodiments of coated pigment powder according to the invention have
9 hydrophobic and lipophilic properties and are also dispersible in silicone fluids.

10

11 The treated pigments have good adhesion to the skin, and ability to permit color
12 pigment of fine particle size to spread well, and is particularly suitable for use in
13 cosmetics such as powder, oil-in-water and water-in-oil emulsions and anhydrous
14 makeup like lipstick.

15

16 DETAILED DESCRIPTION OF THE INVENTION

17 The present invention provides a process for hydrophobizing a variety of cosmetic
18 powders, including pigments, lakes of organic colorant and filler, and formulations in
19 which the such treated powders can be applied. The invention extends to the coated
20 powders produced, to the novel methods of formulating cosmetic products and to the
21 novel cosmetic products that result. In particular, the invention provides novel coated
22 powders, especially but not exclusively cosmetic powders, which, in preferred
23 embodiments of the invention, are highly hydrophobic and uniquely dispersible in
24 both hydrocarbon-based oils, or lipids, and in silicone fluids.

25

26 These desirable properties can be obtained by coating any one or more of a wide range
27 of cosmetic powders with a novel combination of coating agents pursuant to the
28 invention, namely an organometallate and a reactive silicon compound, to provide a
29 durable hybrid coating on the powder particles.

1

2 It is desirable that both coating agents are sufficiently reactive to covalently bond with
3 the target particles, under the conditions of the coating process, to provide a reaction
4 product which is stable to subsequent processing and storage conditions.

5

6 It is preferred that each coating agent residue becomes chemically covalently bound to
7 the surfaces of the powder particles and contributes to the provision of a durable
8 outer layer or skin of a hybrid chemical nature, including metal atoms, silicon atoms
9 and possibly M-O-Si groups, as described herein, which layer or skin envelops each
10 powder particle.

11

12 Preferably at least one of the coating agents comprises a bifunctional coupling agent
13 capable of covalently bonding not only with the target substrate powder but also with
14 the other coating agent, or one of the other coating agents if more than two are
15 employed. To this end, the bifunctional coupling agent may have two or more
16 functional entities, which may be the same or different and which between them
17 provide the desired reactivity with the substrate powder and the other coating agent
18 or materials. More preferably, both coating agents are bifunctional, providing the
19 possibility of oligomeric or polymeric chains comprising residues of both starting
20 materials being present in the coating.

21

22 The beneficial high dispersibility in two different classes of liquid media, coupled with
23 excellent hydrophobicity and water repellency, is especially attractive to formulators
24 in the cosmetics industry enabling the inventive hybrid coated powders to be specified
25 for a wide range of applications without undue concern as to the nature of the liquid
26 phase into which the powder is to be dispersed. Furthermore, the inventive hybrid
27 coatings are suitable for a wide range of cosmetic powders including many or most of
28 the powders used in everyday cosmetic products such as liquid or powder makeups,
29 lipsticks, nail enamels, eye shadows, mascaras and so on. Thus the formulator may

1 freely specify cosmetic powders having the inventive hybrid coatings to meet an
2 exceptionally diversified range of cosmetics requirements. The invention further more
3 enables the formulator to specify one type of coating, the hybrid coating of the
4 invention to be employed for all the powder ingredients of a cosmetic formulation
5 without concern as to the liquid media to be employed in the formulation or as to
6 possible incompatibilities between different coatings.

7
8 Possibly, one of the coating agents, for example the organometallate, may comprise a
9 bifunctional coupling agent, as described above, while the other coating agent, in this
10 exemplary case the silicon-containing compound, is reactive with the one coating
11 agent but not the target powder, for example by way of a hydroxyl substituent. Such a
12 combination can provide a bilayer shell-like coating on the particles comprising for
13 example an outer shell of silicon-containing moieties, being the residues of the silicon-
14 containing compound coupled to the substrate powder through an inner shell of
15 organometallate residues.

16
17 In one preferred embodiment, the invention relates to cosmetic powders treated with a
18 mixture of organotitanate and trialkoxy alkylsilane coating agents to provide a
19 coating that is hydrophobic and lipophilic or lipophobic. The invention also provides
20 processes for the production of such coated powders and cosmetic formulations
21 comprising the cosmetic powders treated with the novel combination of coating
22 compounds or agents.

23 24 Organometallates

25 Any organometallate compatible with the purposes of the invention may be employed
26 in the novel compositions, materials and processes described herein. Many suitable
27 organometallates, and equivalent compounds, additional to those described or
28 suggested herein will be apparent to those skilled in the art in light of the disclosure
29 herein or will become apparent as the art develops. Non-limiting examples of

1 equivalent compounds or compositions are compounds or compositions which
2 function as precursors yielding one or more suitable organometallates *in situ*.

3

4 Organometallate compounds to be employed in the invention are preferably chosen to
5 provide hydrophobic residual units in the powder coating. They may, for example,
6 comprise metallate compounds wherein at least one enduring, unreactive,
7 hydrophobic organic group, such as a saturated hydrocarbon, possibly containing one
8 or more phenyl groups, is each attached to a metal atom by an oxygen atom and at
9 least one displaceable groups or atoms is also attached to the metal atom by an oxygen
10 atom to provide a functional group. The enduring group endures to become a
11 hydrophobic residue in the powder coating while the functional group is removed in
12 the coating process, preferably yielding an M-O group in the coating compound. The
13 residue in the coating should be cosmetically compatible. For this reason,
14 organometallates of toxic metals such as lead, cadmium and mercury are to be
15 avoided.

16

17 To this end the organometallate compounds may comprise one or more relatively
18 unreactive hydrophobic organic groups, e.g. ester groups, covalently bonded to a
19 metal atom, and one or more relatively reactive groups, or functional entities e.g ether
20 or alkoxy groups, also covalently bound to the same metal atom. The ester or other

21

22 The organometallate compound can have from one to five functional entities
23 depending upon the valence state of the metal. However from one to three functional
24 entities is preferred with organometallic compounds having two functional entities for
25 example two alkoxy groups, especially two methoxy or two ethoxy groups, being
26 particularly preferred for use in the practice of the invention. Organometallates with
27 two or more functional entities may be described as "coupling agents".

28

1 Some suitable organometallate compounds for use in the present invention have a
2 structure illustrated by the following Formula 1

3
4
5
6 wherein:

7 R^1 is a saturated, unsaturated or polyunsaturated, straight chain, branched or
8 unsubstituted or substituted cyclic alkyl group having from 1 to 12 carbon atoms,
9 preferably from 1 to 4 carbon atoms;

10 R^2 is a saturated, unsaturated or polyunsaturated, straight chain, branched,
11 unsubstituted cyclic, substituted cyclic alkyl or alkyl phenyl group having from 3 to 60
12 carbon atoms, preferably from 7 to 25 carbon atoms;

13 M is a cosmetically compatible metal capable of forming the compound shown
14 with a valence state of z ; and

15 $x + y = z$.

16 In some useful or preferred embodiments of the invention:

17 R^1 is a saturated straight chain or branched alkyl group having from 1 to 4 carbon
18 atoms, for example, methyl, ethyl or isopropyl;

19 R^2 is a saturated straight chain or branched alkyl group having from 7 to 25 carbon
20 atoms, for example octyl, decyl, stearyl, or cumyl; and

21 M is a metal with a valence state, z , of 2, for example zinc, a metal with a valence
22 state, z , of 3, for example aluminum, a metal with a valence state, z , of 4, for example,
23 tin, titanium or zirconium, or a metal with a valence state, z , of 5, for example
24 vanadium. Metals with a valence state of 3 or higher are preferred.

25
26 In the following description, where reference is made to titanium or to organotitanate
27 compounds it will be understood that other metals or organometallates such as tin,
28 vanadium, zinc and zirconium and their organometallates that are suitable for the

purposes of the invention may be used *mutatis mutandis* in place of titanium or organotitanates, unless the context suggests indicates otherwise.

The organotitanate structures illustrated by Formula 1 and which can be employed in the practice of the invention include, for the case where M is titanium, not only monoalkoxy titanates, but also di- and tri-alkoxy titanates. Monofunctional organometallates, such as monoalkoxy titanates, can couple to the pigment surface and also to suitably functionalized silicones. However, multifunctional organometallates, for example di- and tri-alkoxy titanates, are particularly advantageous for use in the invention for and can provide a number of benefits such as: greater reactivity of the organometallate, for example enhanced ability to bind to the substrate powder; ability to catalyze reaction of functionalized silicon compounds with substrate the substrate powder and with the titanate; and the ability to crosslink with reactive silicon compounds.

Some limited polymerization of multifunctional organometallates may occur with bonding of the resultant oligomers or polymers to the powder substrate. However, it is believed that such organometallate oligomers or polymers in many cases may not be sufficiently stable to yield residues in the end-product coated powders or may not survive post-processing, for example formulation into creams or lotions.

Some suitable hydrophobizing organometallate compounds for use in the practice of the present invention include organotitanate compounds of the following Formula 2:

1

2 wherein:

3 m is from 1 to 4; and

4 n is from 7 to 25, preferably from 12 to 20.

5 The length of each fatty acid chain may be the same or different.

6

7 It will be understood that other suitable organometallate compounds can be employed
8 wherein in Formula (2) titanium is replaced by a suitable metal such as aluminum, tin,
9 vanadium, zinc or zirconium with the formula being adjusted for the metal valence
10 state, as may be necessary, for example by adjusting the number of ester groups, the
11 alkoxy group being retained. Thus, suitable organoaluminates, organostannates,
12 organovanadates, organozincates or organozirconates may be employed

13

14 Some specific organometallates suitable for use in the invention include: liquid
15 monoalkoxy (C_1 to C_{20}) isostearoyl titanates, especially isopropyl triisostearoyl
16 titanate; isopropyl dimethacryl isostearoyl titanate and isopropyl dimethacryl
17 isostearoyl titanate and coordinate titanates such as tetraisopropyl (di(dioctyl)
18 phosphito titanate and tetra (2,2 diallyloxymethyl) butyl, di(ditridecyl) phosphito
19 titanate; organotitanates disclosed in "*The Chemistry of Titanate Coupling Agents*",
20 pages 2-9 and 26-29 in "Ken-React Reference Manual--Titanate, Zirconate and
21 Aluminate Coupling Agents", Monte et al., M. Schlossman U.S. Pat. No. 4,877,604; and
22 the titanate coupling agents disclosed in Monte et al. U.S. Pat. No. 4,098,758, the
23 disclosure of each of which references is hereby incorporated herein by reference
24 thereto.

25

26 Other organometallates that may be used include:

27 isopropyl tri(dioctyl) pyrophosphato titanate, di(dioctyl) pyrophosphato
28 oxoethylene titanate, di(dioctyl) phosphato ethylene titanate, di(dioctyl)

1 pyrophosphato ethylene titanate, tetraoctyl titanate di(ditridecyl) phosphite,
2 and dialkoxy bis(triethanolamine) titanate;

3
4 aluminates such as diisopropyl acetoalkoxy aluminate, isopropyl diisostearoyl
5 aluminate, and isopropyl dioctyl phosphato aluminate;

6
7 zirconates such as isopropyl triisostearoyl zirconate, butyl triisostearoyl
8 zirconate, butyl trioleoyl zirconate, isopropyl trilinoleoyl zirconate,
9 di(cumyl)phenyl oxoethylene zirconate, di(cumyl)phenyl dibutyl zirconate and
10 tri(cumyl)phenyl propyl zirconate; and

11
12 vanadate and zincate analogs or equivalents of the foregoing.

13
14 Other coupling agents can also be used with similar effect and advantage, for example,
15 zirconate or aluminate coupling agents such as neopentyl (diallyl) oxyl, tri(dioctyl)
16 phosphito zirconate and equivalent aluminates. However, titanates constitute a
17 preferred species. Furthermore, analogous titanate coupling agents having different
18 proportions of hydrolyzable to non-hydrolyzable groups from those disclosed by
19 Monte, can be used. There is a great diversity of substituents that can be present on
20 the coupling agent. Some examples of these are set forth in Monte (*supra*). Others will
21 be apparent to those skilled in the art in light of the disclosures herein. Still others
22 may become apparent as the art develops.

23
24 Still further organometallates providing cosmetically compatible residues that can be
25 employed in the present invention will be known to the art. Some of these further
26 organometallates are disclosed in: Guillissen United States Patent 2,732,320, for
27 example at column 4, lines 25-42; Kohn et al. United States Patent 3,014,826, for
28 example at column 2, lines 17-23; Rauner United States Patent 3,015,637, for example at
29 column 2, line 39 to column 3, line 3; Hartlein United States Patent 3,647,846 (Dow

Corning) for example at column 2, lines 34 to 63; Ona et al. United States Patent 4,399,247, for example at column 4, line 35 to column 5, line 18; the disclosures of which patents are hereby incorporated herein by reference thereto.

If desired, the organometallate may be chelated, for example by a mono- or polydentate chelating ligand or group which can be bonded to the organometallate such, for example, as one or more ethylenically unsaturated groups (e.g. acrylic, methacrylic or vinylic), halogenated groups, hydroxylated groups, carboxylated groups, thiol groups, epoxy groups, ester groups, amine groups, urea groups, urethane groups, acetoacetate groups or a group derived from EDTA and its derivatives. Some examples of possible chelating groups or ligands include carboxylic acids, α -ketones, α -diketones, α -keto esters, α -keto amines, (α - and β -hydroxy acids, amino acids, preferably β -hydroxylated amino acids, salicylic acid and derivatives thereof, some specific examples of which are acetoacetoxymethyl methacrylate, methyl β -hydroxymethacrylate, -N-methacryloyl-L-lysine, 4- or 5-methacrylaminosalicylic acid.

While the invention is limited not by any particular theory, but only by the accompanying claims, it is contemplated that the organometallate compound will catalyze, promote or participate in the binding of the functionalized silicone compound with the substrate powder particles. Such favorable activity is helpful in assuring more complete reaction of the functionalized silicone compound, leading to stable coatings with low proportions of unreacted functional entities. Such higher stability is believed to be of particular value for the coating of pigments in preventing or eliminating color shift over time, a problem which may occur with conventionally coated pigments. Such control of color shift is of particular value in the cosmetics and other industries where high quality and consistent appearances are demanded by end product consumers.

1 Functionalized Silicone Compounds

2 Any suitably functionalized silane, functionalized polysiloxane, functionalized
3 fluorinated or fluoroalkyl silane or polysiloxane, or other appropriate functionalized
4 silicon compound compatible with the purposes of the invention, may be employed as
5 a coating agent in the novel compositions, materials and processes described herein.
6 Preferably, the functionalized silicone compound employed is provided with at least
7 one functional entity capable of covalently bonding to a target pigment surface, either
8 directly or through an organometallate residue, under the reaction conditions
9 employed in the coating processes of the invention.

10

11 A preferred functional entity is a lower alkoxy group covalently bonded directly to a
12 silicon atom and having from one to four carbon atoms. Other functional entities such
13 as halo atoms, preferably chloro, amino groups, imino groups, and/or hydroxyl
14 groups may be employed, as is known to those skilled in the art. Still other functional
15 entities or groups that may be employed if desired, so long as they provide adequate
16 coupling functionality for the purposes of the invention include ethylenically
17 unsaturated groups such as acrylic, methacrylic, vinylic groups or the like,
18 halogenated groups, hydroxylated groups, carboxyl or carboxylated groups, thiol or
19 mercaptan groups, epoxy groups, ester groups, urethane groups, urea groups, amino
20 acid groups, polypeptide groups and so on.

21

22 Furthermore, groups that are largely unreactive in conventional coating processes, for
23 example Si-H groups in polysiloxane compounds, e.g. methicone, may have sufficient
24 reactivity in the presence of the organometallate compounds employed in the present
25 invention to be useful as functional entities. Thus, for example, methicone, having a
26 backbone of methyl hydrogen siloxy groups can be employed as a functionalized
27 silicone compound in the practice of the invention without addition of other functional
28 entities. Equivalent compounds having fewer reactive backbone hydrogen atoms
29 may also be employed.

1

2 It can also be advantageous for the silicone compound to have multiple functional
3 entities, for example methoxy or ethoxy groups, to enable the functionalized silicone
4 compound to become polymerizes, and possibly even crosslinked, as a result of the
5 coating processes of the invention.

6

7 The functionalized silicon compound employed in the coating process of the invention
8 should preferably have a structure which will provide a stable residue on the substrate
9 powder and which will remain stable throughout subsequent processing steps, for
10 example cosmetic formulation steps, that the coated powder is intended to undergo,
11 and will also remain stable for the intended shelf life of the product. The silicon
12 backbone structure of the functionalized silicon compound starting material, and the
13 substituents employed, should be selected with this end in view. Thus, it is preferred
14 that the backbone structure comprise a single silicon atom, a pair of silicon atoms
15 connected by a single covalent bond or a siloxy chain, $-(\text{Si-O})_r$, where r may be an
16 integer of from 2 to 200, or even as high as 1,000. Preferably r is from 5 to 100, more
17 preferably from 10 to 50.

18

19 Preferred substituents in the silicon compound, besides the functional entity or
20 groups, lack chemical reactivity in the processes of the invention and form stable
21 entities in the powder coating. Some examples of suitable such nonfunctional
22 substituents include saturated hydrocarbon groups and saturated fluorohydrocarbon
23 groups, particularly, but not exclusively, alkyl and fluoroalkyl groups. Such
24 substituents can have any number of carbon atoms supporting stable bonding of the
25 substituent or substituents to the silicon backbone, for example, from 1 to about 50,
26 preferably from 4 to about 35 and more preferably from about 7 to about 25 carbon
27 atoms per substituent, preferably with a maximum of 50 carbon atoms per silicon
28 atom. It will be understood that increasing the carbon count of the substituent or
29 substituents may enhance the lipophilicity of the inventive coated powders. However,

this consideration will need to be balanced against the instability of larger substituents which may dissociate. Another balancing consideration is that for enhanced silicone dispersibility, higher proportions of silicon atoms in the coating may be desirable.

Many suitable functionalized silicon compounds, and equivalent compounds, additional to those described or suggested herein will be apparent to those skilled in the art in light of the disclosure herein or will become apparent as the art develops.

Some suitable functionalized silane compounds for use in the present invention have a structure illustrated by the following Formula 3:

wherein:

R^3 is methyl, ethyl, propyl or butyl;

R^4 is a saturated, unsaturated or polyunsaturated, straight chain, branched, unsubstituted cyclic, substituted cyclic alkyl or alkyl phenyl group having from 3 to 60 carbon atoms, preferably a saturated alkyl group having from 7 to 25 carbon atoms;

and $x + y = 4$.

The structures depicted include mono- and dialkoxy silanes in addition to trialkoxysilanes, all of which can react with pigment surfaces. However, di- and trialkoxy silanes are particularly advantageous for their abilities to form polymers (or oligomers) and crosslinked networks which are chemically and physically stable. In practice, trialkoxysilanes, such as those specifically mentioned herein are particularly suitable for employment in the invention being active and commonly used as functionalized silicon coating materials.

Some preferred functionalized silicon compounds for use in the practice of the invention have the following Formula 4:

wherein R^3 and n are the same as above and preferably R^3 is methyl or ethyl and n is from 7 to 25.

Some examples of suitable functionalized silanes include: organoalkoxysilanes having an organic group or groups which may be unsubstituted or substituted or a mixture of different groups including for example, methyltrimethoxyalkylsilane, phenyltrimethoxyalkylsilane, and diphenyldimethoxy alkylsilane, as well as silanes having aryl-substituted organic groups, for example, gamma-methacryloxypropyltrimethoxysilane wherein the alkyl group preferably has from 7 to 25 carbon atoms, more preferably from 8 to 12 carbon atoms and the aryl group is preferably a saturated hydrocarbon, save for benzene ring unsaturation, for example phenyl or alkylphenyl with up to 25 carbon atoms.

Functionalized silicon compound coating agents, or starting materials, employable in the invention can include suitable polysiloxanes such for example as a polysiloxane compound of the following Formula 5:

wherein:

R⁵ is CH₃ or H;

X is H or OH; and

q is from 1 to about 1,000, preferably not more than about 100 and more preferably from about 5 to about 60.

The R⁵ substituents can all be hydrogen or all be methyl with the presence of hydrogen rather than methyl being desirable for higher values of q to provide additional reactive sites. Alternatively, the R⁵ substituents can be a mixture of hydrogen and methyl groups, for example a 1:1 mixture. The mixture can be any desired proportion of the two substituents, for example from 3:1 to 1:3. "Mixture" is here used to indicate that one or more siloxy units has a hydrogen substituent at R⁵, and one or more siloxy units has a methyl substituent at R⁵.

This structure includes three classes of polysiloxane compound that are commonly used to coat pigments especially cosmetic pigments, namely: methyl hydrogen polysiloxane wherein X = H and R = CH₃; methyl hydrogen polysiloxane and dimethylpolysiloxane copolymer wherein X = H, R = CH₃ or H; and dimethiconol wherein X = OH, R = CH₃. Compounds containing methyl hydrogen polysiloxane can bond chemically to the powder substrate by reaction of a Si-H group while dimethiconol can bond to the pigment, or other powder, chemically via crosslinking through reaction with a di- or tri-alkoxy titanate. Suitably functionalized dimethicone compounds may also be employed, with either backbone or terminal functional substituents. Useful functionalized polysiloxanes can comprise from about 1 to about 100 siloxy groups per functional group, desirably from about 3 to about 20 siloxy groups per functional group.

1
2 The polysiloxane compounds, groups or units employed in the invention or generated
3 in the coating may include polymeric chains having up to 100 or even up to 1,000
4 repeating -Si-O- units, wherein at least one Si atom of each chain is linked to the
5 powder surface through an oxygen atom. The chains can be cross-linked to each other
6 as well. The remaining functional sites of each Si atom in the chain can be occupied by
7 a variety of groups as will be apparent from this disclosure, including hydrogen,
8 methyl, $\text{C}_2\text{-C}_{30}$ alkyl or alkenyl, and/or phenyl, and equivalents thereof, resulting in
9 units such as $\text{-Si(CH}_3\text{)(C}_6\text{H}_5\text{)O-}$, $\text{-Si(CH}_3\text{)(H)O-}$, or $\text{-Si(H)(C}_6\text{H}_5\text{)O-}$, and generally
10 capped with $\text{-Si(CH}_3\text{)}_3$.

11
12 Some further examples of embodiments of functionalized silicones useful in the
13 practice of the invention include alkoxy-substituted branched silicones of
14 intermediate size, having for example from about 10 to about 100 siloxy groups per
15 molecule, preferably from about 15 to about 40 siloxy groups per molecule.
16 Optionally, such a branched silicone can have a relatively long backbone of for,
17 example from about 4 to about 50 siloxy units, preferably from about 8 to about 30
18 siloxy units, with a small number of side chains, for example from about 1 to about
19 10 side chains, preferably from 2 to 5 side chains. The side chains can have the
20 same or different numbers of siloxy groups, for example from about 1 to about 12
21 siloxy groups, preferably from 3 to 8 siloxy groups.

22
23 Such a branched silicone can be functionalized with a small number of alkoxy
24 groups, e.g. methoxy or ethoxy groups, preferably methoxy groups, for example
25 from about 1 to about 10 alkoxy groups, preferably from 2 to 5 alkoxy groups.
26 Preferably, the alkoxy groups are not terminal groups, although some could be, and
27 preferably they are attached to the backbone of the branched silicone. However, in
28 other embodiments one or more alkoxy groups can be attached to one or more side
29 chains, if desired.

1

2 In still further embodiments of such branched silicones one or more, or all, of the
3 alkoxy groups can be replaced by another suitable functional group as described
4 herein, for example a chloro group.

5

6 The siloxy groups are preferably dimethylsiloxy groups, or possibly
7 diethylsiloxy groups although other lower alkyl groups, e.g. up to about 10 carbon
8 atoms may be attached to the silicone atoms, if desired, as will be apparent to those
9 skilled in the art. A small number, e.g. less than 10, of the siloxy groups may be
10 methyl hydrogen siloxy groups if desired. If methyl hydrogen siloxy groups are
11 employed fewer or no alkoxy or other functional substituent may be required.

12

13 One specific example of a suitable such branched silicone compound is product KF-
14 9908 supplied by Shin-Etsu Chemical Co., Ltd. (Tokyo, JP) which is believed to have
15 the following formula (6)

16

17

18

19

20

21

22

23

24 wherein each node or angle represents an oxygen or silicon atom and the siloxy
25 chains are methyl-terminated dimethyl siloxy chains. The -OR groups are methoxy
26 or ethoxy.

26

27 Some alternative embodiments of branched silicone compound useful in the
28 practice of the invention are similar to those just described with the addition of a
29 number of alkyl side chains attached to the siloxy backbone, of length of from about

1 1 to about 30 carbon atoms. Optionally the alkyl side chains can be interposed
2 between the siloxy side chains to alternate with the siloxy side chains. An example
3 of such a compound is product KF-9909 available from Shin-Etsu Chemical Co.

4
5 A still further alternative group of compounds constituting functionalized silicone
6 compounds useful in the practice of the invention comprise compounds complying
7 with formula (6) as described above, wherein the backbone or main chain is a
8 polyacrylate chain rather than a polysiloxane chain, the side chains being siloxy chains,
9 as described above, rather than alkyl groups. The acryl monomers of the polyacrylate
10 backbone can have from about 1 to about 10 carbon atoms, preferably from 2 to 5
11 carbon atoms.

12
13 Employment of polyfunctional silicon starting materials having more than two
14 functional entities per unit can provide a crosslinked coating of exceptional durability.

15
16 Many suitable functionalized silicone compound starting materials, comprising one or
17 more functionalized silicone compounds, that are useful in the practice of the
18 invention are known and some are described, by way of example in: Law, et al. United
19 States Patent 4,113,665 (Ameron), for example at column 2, lines 13 to 47 and column
20 3, line 17 to column 7, line 19; Socci, et al. United States Patent 4,832,944 (Revlon), for
21 example, at column 2, lines 21-51; Hollenberg, et al. United States Patent 5,143,722, for
22 example at column 2, line 43 to column 3, line 62; Hasegawa United States Patents
23 5,368,639 and 5,458,681 (Miyoshi Kasei), for example at column 2, line 24 to column 2,
24 line 48 of the '639 patent; Mitchnick, et al. United States Patent 5,486,631 (Siltech and
25 SunSmart), for example at column 2, line 49 to column 4, line 38; Mitchnick, et al
26 United States Patent 5,536,492 (Siltech and SunSmart); Horino, et al. United States
27 Patent 6,200,580 (Miyoshi Kasei) for example at column 3, lines 33-53 and column 6,
28 line 55 to column 7, line 67; and Colton, et al. United States Patent Application
29 20020061407 (PPG) for example at paragraphs [0020]-[0022]. The specific passages

1 cited, as well as the entire disclosures, of each of the patent publications identified in
2 this paragraph are hereby incorporated herein by this specific reference thereto.

3
4 Some other suitable functionalized silicone compound starting materials useful in the
5 practice of the invention include fluorinated or alkyl fluorinated analogs of the silicone
6 compounds described in the foregoing patents, which fluorinated or alkyl fluorinated
7 analogs can, without this being a requirement, have the desirable structural
8 characteristics for fluorinated or alkyl fluorinated functionalized silicone compound
9 starting materials to be employed in the present invention that are described
10 hereinbelow.

11
12 The invention also includes the modification of known silicone coating processes and
13 products such as those described in the foregoing patents or other literature, by the
14 inclusion of an organometallate in the described silicone coatings or processes to
15 provide hybrid silicone-organometallate coated powders. Furthermore, the present
16 invention can include in its processes and products the use of reagents, reactants,
17 reaction conditions and treatment methods and steps described in the foregoing
18 patents or other literature for the purpose of coating powders with silicon- containing
19 materials, as will be understood by those skilled in the art in light of the teachings
20 herein.

21 22 Fluoro- and Fluoroalkyl Silicon Compounds

23 If desired, the functionalized silicon compound starting material may be fluorinated
24 and thereby provide fluoro substituents in the powder coating. Fluorinated silicon
25 compounds have excellent hydrophobicity but relatively poor affinity for lipids, are
26 expensive and may be unstable at an alkaline pH.

27
28 Such fluorination, or perfluorination wherein a carbon atom is fully fluorinated, may
29 comprise one, two, three or more fluoro substituents each in one or more hydrocarbon

1 groups, being groups attached directly to a silicon atom in the silicon compound. If
2 saturated, which is preferred in the practice of the invention, such fluorohydrocarbon
3 groups may be expected to manifest themselves in the coating agent in a chemically
4 unchanged state. In one embodiment, the functionalized silicon compound comprises
5 a single fluoroalkyl group having not more than about 30 carbon atoms and from 1 to
6 about 12 fluorine atoms.

7
8 Alternatively, the fluorination of the silicon compound could comprise one or two
9 fluorine atoms bonded directly to a silicon atom. However, Si-F groups are less
10 preferred because the resultant residue in the coating may have undesirable reactivity.

11
12 Some embodiments of the invention can employ as starting materials one or more
13 fluorosilane compounds having the structure shown in the following Formula 7:

16
17 wherein:

18 R^1 is as defined above, broadly stated, a 1-12 carbon hydrocarbon;

19 b is 1, 2 or 3;

20 $b + c = 4$;

21 d is from 0 to about 3; and

22 e is from about 3 to about 20.

23

24 It will be understood that other functional groups than the alkoxy groups can be
25 employed if desired and that the fluoroalkyl group shown may be used in other
26 compounds where a fluoroalkyl group, has been referenced or would be seen to be
27 suitable herein.

28

1 In addition suitable fluorinated functionalized silicone compounds that can be used in
2 the practice of the invention are disclosed in: Farer United States Patent 6,471,950, for
3 example at column 2, lines 30-63; Goodwin United States Patent 5,328,768 (PPG), for
4 example at column 2, lines 6-25; and O'Lenick Jr. et al. United States Patent 6,524,705
5 (Phoenix Research) for example at column 2, lines 38-63 and column 4, lines 37-48.

6
7 In addition, fluorinated silicon compounds or fluorosilanes such as those disclosed in
8 United States Patent 5,473,038 O'Lenick, Jr. (Siltech) and Arnaud United States Patent
9 6,203,780 (L'Oreal) can be employed as starting materials for the coating processes of
10 the present invention when suitably functionalized by the inclusion in the molecule, if
11 not already present, of one or more functional groups, for example hydroxy, methoxy
12 or ethoxy groups, as has been described herein with reference to non-fluorinated
13 compounds. Two or three such groups are preferred to provide for the possibility of a
14 polymerized residue in the coating.

15
16 The entire disclosures of each of the foregoing patent publications relating to
17 fluorinated silicon compounds are hereby incorporated herein by this specific
18 reference thereto.

19
20 It will be understood that the above-described fluorinated functionalized silicon
21 compounds can be employed in the processes of the invention in place of or as well as
22 the nonfluorinated functionalized silicon compounds to yield coatings including
23 fluorinated groups. If desired, the fluorinated functionalized silicon compounds
24 admixed with, or otherwise combined with the nonfluorinated functionalized silicon
25 compounds, as coating agents, in approximate proportions of from 1:10 to 10:1.

26 27 Hydrocarbon Substituents

28 It will be understood that possible hydrocarbon groups in the organometallate or
29 functionalized silicon compound can have a variety of structures and may, for

1 example, include, independently of each other, if the molecule contains more than one
2 hydrocarbon group, a linear or branched alkyl group, a cycloalkyl group, a substituted
3 or an unsubstituted aryl group or combinations of the foregoing. Preferably, such
4 groups are selected to provide residues having little or more preferably no significant
5 reactivity in the end product coated powder.

6
7 If desired, either or both the organometallate or the silicon compound can contain one
8 or more functional coupling groups, or atoms intended to provide a bond to the
9 substrate powder or to the other of the organometallate or the silicon compound,
10 which functional entity is borne by a hydrocarbon or fluorohydrocarbon substituent,
11 for example an alkyl or fluoroalkyl group. Such an alkyl substituent functional group
12 may for example be an ethylenically unsaturated group such as an acrylic,
13 methacrylic, vinylic group or the like, a halogen or halogenated group, a hydroxyl or
14 hydroxylated group, a carboxyl or carboxylated group, a thiol or mercaptan group, an
15 epoxy group, an ester group, a urethane group, a urea group, an amine or amino acid
16 group, a polypeptide group or the like. Where the carrier group for the functional
17 entity is a fluoroalkyl or other fluorohydrocarbon group, it is preferred that there is at
18 least one carbon atom, more preferably at least two carbon atoms between the carbon
19 atom bearing the functional entity and the closest carbon atom bearing a fluorine
20 atom.

21
22 However, in most cases, for the purposes of the invention it is believed preferable for
23 the functional entity to be bonded directly to a, or the, metal atom of the
24 organometallate or to a silicon atom of the silicon compound, or at least to be not
25 unduly remote from same. Accordingly, where a functional entity intended for
26 coupling in the coating process of the invention is borne by a hydrocarbon substituent,
27 it is preferred that the functional entity be attached to the fifth or fewer carbon atoms
28 from the metal atom, preferably to an adjacent or next adjacent carbon atom.

29

1 Solvents

2 Suitable solvents for the coating agents may be employed to facilitate the coating
3 process, if desired. Such solvents should be capable of dissolving the respective
4 coating agent to promote even distribution of the coating agent over the surface of the
5 substrate powders in a mixing step and of being removed in a drying step. For
6 example, water or other suitable solvent may be employed for the organotitanate or
7 other organometallate, as described in Schlossman '604 and a suitable aprotic solvent
8 can be employed for the functionalized silane or other silicon compound. Also, if
9 desired, the organometallate, and optionally also the silane, can be solubilized in a
10 volatile organic solvent such as isopropyl alcohol, heptane, isoheptane, isooctane,
11 isononane and petroleum distillates such as those available from Phillips Chemical
12 under the trade names or trademarks Soltrol 130, Soltrol 150 and Soltrol 170. and then
13 mix it with or spray it on the materials to be coated.

14
15 Another useful solvent for functionalized silicon compounds is an isopar solvent.
16 Isopar solvents are a range of solvents each comprising a high-purity, fractionated
17 partially neutralized mixture of isoparaffinic acids which are available in different
18 grades such as isopar C, which comprises C7-C8 solvents, isopar E or isopar G.

19
20 Preferably, a single solvent, for example isopar C, or a mixture of solvents, is used to
21 dissolve both the organometallate and the functionalized silicon compound in a single
22 homogenous liquid medium. However, an emulsion of two or more solvents could be
23 employed, with different coating agents dissolved in each solvent, on a one-to-one
24 basis.

25
26 Cosmetic Powders

27 Some suitable cosmetic or other powders that can be employed in this invention
28 include: inorganic and organic pigments and fillers; talc; mica; sericite; kaolin;
29 starches; barium sulfate,, calcium carbonate; porous or non-porous silica in various

1 shapes including spherical, ellipsoidal, irregular, rod and other known shapes;
2 hydroxyapatite; and hollow or solid polymeric powders or microspheres of
3 polymethylmethacrylate, polyvinylidene chloride copolymer, polyethylene, cellulose
4 or nylon or other suitable polymer. Other suitable cosmetic or other powders will be
5 known or be or become apparent to those skilled in the art.

6

7 The powders employed as substrates in the processes of the invention may have any
8 desired regular or irregular shape including spherical or ball like particles with
9 irregular porous surfaces, needles, rods, flakes, rhomboids and so on.

10

11 Some suitable inorganic pigments which may benefit from the hybrid coatings of the
12 present invention include: titanium dioxide; zinc oxide; iron oxide; alumina oxide;
13 chromium oxide; mango violet; ultramarines, composites of metal oxides or of a metal
14 oxide and an inorganic salt and any other inorganic pigment powder useful in the
15 cosmetic or other relevant arts. If desired, prior to the inventive coating treatment,
16 powders such as titanium dioxide, zinc oxide and other inorganic pigments or fillers,
17 may be treated with silica, alumina, boron nitride or other known inorganic coatings,
18 singly or in combinations.

19

20 Some suitable organic pigments include aluminum, barium, calcium and zirconium
21 lakes of FD&C and D&C grades of Red No. 6, Red No. 7, Red 21, Red No. 27 and
22 Yellow No. 5. Other suitable inorganic or organic pigments will be known or be or
23 become apparent to those skilled in the art.

24

25 Preferably, the reactants and reaction conditions employed in the coating processes of
26 the invention are selected to provide covalent bonding to metal oxide, hydroxide,
27 carbonate, silicate or other reactive moieties on the surfaces of the cosmetic powder
28 particles. However, ionic, hydrogen or van der Waals bonding in addition to, or in

1 the alternative, may also provide satisfactory bonding between the coating and the
2 substrate powder particle.

3
4 Particle Size

5 There is no particular limitation as to the particle size of the powders employed in the
6 invention. However, a mean particle size in the range of from about 0.01 to about 100
7 micron is preferred and a mean particle size in the range of from about 0.01 to about
8 20 micron is more preferred. Desirably, at least about 90 percent, preferably at least
9 about 98 percent, and more preferably at least about 99.5 percent of the particles lie
10 within the preferred average particle size range. Some preferred powders for use in
11 the invention are free of oversize particles that may impart grittiness and are also free
12 of overly fine particles whose presence may be undesirable in the processes of the
13 invention described herein.

14
15 Proportions

16 The quantity, or proportion of hybrid coating material employed in the present
17 invention can be varied according to the nature of the substrate and can be selected to
18 provide a coated pigment or other cosmetic powder having good water repellency,
19 smooth feel and good adhesion to the skin. To this end, the quantity of coating agent
20 should generally be at least 0.1 percent of the coated product. If the amount is over
21 about 30 percent by weight, the coated powder may be too wet and may tend to
22 agglomerate unacceptably. Thus, in one embodiment the quantity is in a range of
23 from about 0.1 to about 30 percent by weight based on the weight of the coated
24 powder, preferably from about 1 to about 10 percent and more preferably from about
25 2 to about 5 percent of the weight of the coated powder.

26
27 The relative proportion, or ratio, of organometallate to silane can be varied according
28 to the balance of properties desired. Thus, the hydrophilicity may be increased by
29 increasing the proportion of organometallate relative to the silane and the silicone

1 fluid dispersibility can be increased by increasing the proportion of silane relative to
2 the organometallate. Thus, the ratio of organotitanate or other organometallate to
3 silane can be in a range of about 0.1:1 to 10:1, but is preferably in a range of about 0.4:1
4 to about 3:1. A proportion within about ten or twenty percent of equality is useful to
5 provide a balance of properties.

6
7 Coating Process

8 In one embodiment of a process aspect of the invention, the invention provides a
9 cosmetic powder hydrophobizing process comprising:

- 10 a) combining:
- 11 i) a powder to be coated;
 - 12 ii) a liquid dispersion medium sufficient for a slurry;
 - 13 iii) an organometallate compound of formula (1); and
 - 14 iv) a functionalized silicon compound;
- 15 to form a slurry;
- 16 b) thoroughly mixing the slurry;
 - 17 c) filtering the slurry; and
 - 18 d) heating the resultant paste to a temperature and for a time effective to yield a
19 dry powder.

20
21 Some examples of suitable elevated temperatures are in the range of from about 60 to
22 about 130 °C, and of suitable times in the range of from about two to about ten
23 hours. Other suitable times and temperatures will be known to those of ordinary skill
24 in the art, having regard to the materials employed, or can be determined without
25 undue experimentation. Optionally drying may be conducted under vacuum..

26
27 The slurry may be prepared in a variety of ways, as will be apparent to those of
28 ordinary skill in the art. For example, a blend of the organometallate and the
29 functionalized silicon compound coating agents can be added to the powder to be

1 coated and a suitable liquid medium to form a slurried mixture. Alternatively, the
2 coating agents may be dissolved in one or more solvents, which optionally may be
3 emulsified and mixed or sprayed on to the powder. Preferably, a single solution of a
4 blend of the two coating agents, each of which may comprise one or more compounds,
5 e.g. compounds of formulae I and II, respectively, is mixed with the powder or
6 powders to be coated, preferably by spraying on to the powder while mixing.
7 However the ingredients are brought together, it is desirable to thoroughly mix the
8 slurry until homogeneity is achieved, with a view to ensuring that the entire surface of
9 each powder particle is wetted.

10

11 Any suitable additives that are customary employed in pigment coating processes
12 may be included in the mixture, if desired. For example, various acids, including low
13 molecular weight aqueous organic acids, such as acetic acid, can be used to catalyze
14 the hydrolysis of functionalized silane starting materials. Also, trivalent iron 2-
15 ethylhexanoate or zinc 2-ethylhexanoate can be employed to catalyze reaction of
16 methicone with substrate powder materials. However, in many cases use of such
17 additives or catalysts is not necessary.

18

19 If desired, the dried, hybrid-coated powder produced by this process can be
20 pulverized in a mill, for example a jet mill, hammer mill, or other suitable mill.

21

22 The resultant alkylpolysiloxane, or alkylpolysiloxane residue, in the hybrid powder
23 coating preferably has a degree of polymerization of from about 5 to about 100, more
24 preferably from about 10 to about 15.

25

26 Other processes for producing hybrid coated powders pursuant to the present
27 invention include a two-stage process wherein the powder is first coated with the
28 organometallate and is then coated with the functionalized silicone compound. If
29 desired, the organometallate powder may be dried prior to coating with

1 functionalized silicone compound. Preferably, such intermediate drying step is
2 curtailed or moderated to avoid fully curing the organometallate residues so that the
3 organometallate coated powder particles retain sufficient surface reactivity to
4 effectively bond with the functionalized silicone compound in the second stage of the
5 process. The intermediate drying step is followed by a final drying step, to completely
6 cure the hybrid coating, after the functionalized silicone compound has been applied.
7 Such a two-stage process is contemplated as providing an outer surface of the hybrid
8 coated powder particle which is particularly rich in silicon atoms and accordingly has
9 excellent silicone fluid dispersibility.

10
11 Alternatively, the functionalized silicone compound could be applied in a first stage
12 prior to application of the organometallate in a second step, with or without the
13 intermediate drying step. However, the good reactivity of preferred
14 organometallates and their ability to bind effectively with both pigment powder
15 surfaces and many silicone materials renders the application of the organometallate
16 prior to the functionalized silicone compound a particularly attractive two-stage
17 process. Such process is believed preferably to coating with organometallate before
18 silicon because the organometallate may be less resistant to heat. Furthermore,
19 application of the organometallate on to a silicone coated powder substrate is believed
20 advantageous in reacting with residual reactive groups that may remain in the silicone
21 coating, especially on the outer surface thereof.

22
23 Optionally each stage may employ a suitable solvent for the respective coating agent,
24 which solvent is sufficiently volatile to be removed by drying.

25
26 Preferably, the herein described coating agents are the only reactive coating materials
27 employed. Thus, the reactive coating materials employed in the coating compositions
28 and processes of the present invention preferably consist essentially of an

organometallate and a functionalized silicon compound each of which may be one or more of the respective compounds described herein as being useful coating agents.

Coating Structure

Possible chemical structures of the inventive hybrid powder coating are more fully described hereinbelow. Preferred coatings comprise a continuous, complete, coherent coating over the entire outer surface of each powder particle which coating is tenaciously covalently bonded to the powder substrate. Preferably, also the coating has at least one covalent bond to the powder particle substrate for every 100 metal or silicon atoms in the coating agent, more preferably for every 20 such atoms, and still more preferably for at least every 10, or even 5 such atoms.

It will be understood that an alkylpolysiloxane coating agent can provide a residue in the powder coating in the form of a chain of siloxy units. These siloxy units may be terminated with, or interspersed with, organometallate units, may have varying degrees of crosslinking and will have at least some terminal units bonded to the powder substrate. Other terminal units may be capped with organometallate groups or may, in some cases, comprise free hydroxyl groups.

One embodiment of coating according to the invention can have the following structural formula (8), employing titanium as an exemplary metal:

wherein a is from 1 to 1000, preferably from 1 to 100. The particular value of a will depend upon the starting materials and reaction conditions employed, as will be apparent to those skilled in the art. The structure shown can repeat throughout the

1 coating. The unsatisfied valencies can be occupied by other similar units, some of
2 which may serve as cross links, e.g. through oxygen atoms, powder substrate atoms or
3 groups, or any of the various residual groups described or implicit herein. Valencies
4 not made to other units are preferably satisfied with hydrocarbon or
5 fluorohydrocarbon groups or fatty acid ester groups, as will be apparent from the
6 disclosure herein. Although only one Si-O-Ti group is shown, in some instances
7 multiples of this group may also chain together. However such poly(siloxy-metal)
8 chains are not generally believed to be present to a significant extent in the resultant
9 coatings.

10
11 Reaction of the organotitanate coating agent with a silicone as well as the coated
12 powder can provide a structure in the finished coating comprising -Si-O-Ti- units in
13 addition to the conventional polysiloxane backbone units -Si-O-Si-. Thus, such
14 coatings of the present invention have a quite different chemical character from
15 conventional silicone coatings.

16
17 Organometallate starting materials having only a single functional entity can be
18 expected to yield coatings wherein single organometallate units are covalently bound
19 to the powder surface and to multifunctional siloxy units that are also covalently
20 bonded to the powder surface, if such siloxy units are present.

21
22 If both the organometallate compound and the functionalized silicon compound are
23 unifunctional, then the coating can be expected to consist essentially of a mosaic of
24 single units of each compound which preferably extends continuously, without
25 interruption, over the surface of each cosmetic powder particle. The relative affinities
26 of the coated particles for lipids or silicone fluids will depend upon the relative surface
27 areas the two different units occupy as well as the particular hydrophobic or silicic
28 character of the respective units. In turn, the relative surface areas occupied can be
29 expected to depend upon the molecular sizes and reactivities of the respective starting

1 materials. The respective dispersibilities of the inventive hybrid coated powders in
2 lipids and silicones can be adjusted by varying these parameters as may be
3 determined empirically by the simple experiments described herein.

4
5 Organometallate starting materials having two or more functional entities, e.g. two
6 alkoxy groups, can be expected to yield coatings which in addition to the features
7 described in the immediately preceding paragraph include siloxy units coupled to the
8 particle surface through an organometallate unit. Possibly, di-, tri- or
9 polyorganometallate units may bond to the particle surface. However such structures
10 are believed to have only limited stability under most relevant reaction conditions and
11 to fairly readily break down to yield a single organometallate unit bonded to the
12 powder surface.

13
14 Of particular interest in the practice of the invention are coated powders formed from
15 difunctional organometallate compounds and difunctional silicon compounds. The
16 resultant coatings can include chains of polysiloxy units coupled to the powder, and
17 possibly also interconnected one to another, by metallate units and may contain -Si-O-
18 M- units wherein valencies not shown are satisfied with substituents present in the
19 starting materials, for example alkyl or ester groups. Such structures are believed
20 desirable in providing durable and cohesive coatings that are tenaciously bonded to
21 the cosmetic powder particles.

22
23 While the invention is neither bound nor limited by any particular theory, but only by
24 the appended claims, it is known, for example from DuPont Tyzor® Organic
25 Titanates, Dupont Specialty Chemicals, 11/93, 233629A, that organic titanates are
26 useful for the catalysis and crosslinking of silicones and can catalyze polymerization of
27 various siloxanes for coatings, providing harder surfaces, improved heat and electrical
28 resistance, adhesion, water repellency and resistance to heat and staining. However,
29 that cosmetic powders could obtain improved dispersibility in oils and silicone fluids

1 as a result of the hybrid coatings of the present invention was neither known or
2 suggested. Based on the aforementioned knowledge, it is contemplated that the
3 incorporation of organometallates in the inventive coatings may result in a more
4 complete reaction of compounds such as methyl hydrogen polysiloxane or methyl
5 hydrogen polysiloxane and dimethylpolysiloxane copolymer with pigment, e.g. more
6 complete reaction of their Si-H groups, lowering the potential for the generation of
7 hydrogen over time, for example during storage, by the coated pigment.

8
9 Furthermore, complete, or essentially complete, reaction of functionalized silicon
10 compounds such as methyl hydrogen silicone may be effective in reducing or
11 eliminating problems of color shift, possibly by reducing long term surface reactivity
12 and resultant particle agglomeration.

13
14 It will be understood that each of the organometallate and functionalized silicon
15 starting materials may itself constitute a mixture of materials of various functionality,
16 with the resulting coatings having a blend of the above-described structures.

17
18 It will also be understood that whereas the structures of the novel powder coatings of
19 this invention, and possibly also of some of the starting materials, are described in
20 terms of covalent bonds, such descriptions may be idealized and the actual chemical
21 structures may and probably will display some characteristics of ionic, hydrogen and
22 van der Waals bonding, without departing from the teachings herein.

23
24 The invention also includes a lipid- and silicone-dispersible coated cosmetic powder
25 comprising cosmetic powder particles and a hydrophobic coating on the cosmetic
26 powder particles, the hydrophobic coating conferring lipid and silicone dispersibility
27 on the cosmetic powder particles and comprising:

28 a) cosmetically stable hydrophobic organometallate units of formula $(R^6)_gM_1-O-$
29 wherein:

1 M₁ is a metal capable of forming cosmetically stable organometallate
2 compounds of the structure shown, including any of the metals M;
3 a equals the valence state of metal M₁ minus 1 or minus 2, wherein, in the case
4 of the latter alternative, the available valence of metal M₁ is covalently bonded
5 to another M₁ atom or to a coating material oxygen atom;
6 R⁶ is a hydrophobic organic moiety including a cosmetically stable covalent
7 bond to metal M or, when a is greater than 1, to an oxygen atom with an
8 available valence and wherein multiple R⁶s, if present, may be the same or
9 different; and

10 b) cosmetically stable siloxy units of formula D-R⁷-R⁸-Si-O-, "Formula (9)"
11 hereinafter, wherein:

12 D is an oxygen atom with an available valence or a hydrophobic organic moiety
13 including a cosmetically stable covalent bond to the silicon atom; and

14 R⁷ and R⁸ may be the same or different and are each a hydrophobic organic
15 moiety including a cosmetically stable covalent bond to the silicon atom;
16 wherein the hydrophobic coating is covalently bonded to the cosmetic powder by
17 satisfaction of available oxygen valencies in the organometallate and siloxy units.

18
19 Some preferred embodiments of R⁷ and R⁸ include optionally saturated hydrocarbon
20 or fluorohydrocarbon groups having from 1 to 30 carbon atoms and other such groups
21 as will be apparent from the disclosure herein. Other possible groups for D include
22 the same groups as for R⁷.

23
24 The organometallate units in Formula (9) include units having two available oxygen
25 valencies, at least one of the two organometallate unit available oxygen valencies
26 being satisfied by a covalent bond to one of the siloxy units or to another
27 organometallate unit, and the hydrophobic coating can include siloxy units bonded to
28 the powder through organometallate units.

29

1 The siloxy units in Formula (9) include units having two available oxygen valencies at
2 least one of the two siloxy unit available oxygen valencies being satisfied by a covalent
3 bond to one of the siloxy units or to another organometallate unit and the hydrophobic
4 coating can include polysiloxo units.

5
6 Both the organometallate units and the siloxy units in Formula 7 can include units
7 having two available oxygen valencies and the hydrophobic coating includes poly
8 siloxy units bonded to the powder through organometallate units.

9
10 The coating can comprise a stoichiometric proportion of organometallate units to
11 siloxy units of from about 0.05:1 to about 10:1, preferably about 0.4:1 to about 3:1.

12
13 Some embodiments of the invention, and of making and using the invention, are
14 described, without limitation, in the following examples which in conjunction with the
15 foregoing description include the best mode contemplated of carrying out the
16 invention.

17
18 Comparative Example A: Isopropyl Titanium Triisostearate-coated TiO₂

19 98 g of titanium dioxide powder, product code X200 from Kemira Corporation, are
20 added to a blender. 5.9 g of a 34% wt/wt solution of isopropyl titanium triisostearate
21 (referenced "ITT" hereinafter) in isopar C are sprayed on the titanium dioxide powder
22 in the blender under agitation. The slurry mixture is thoroughly blended, transferred
23 to a tray and dried at 110 °C for 4 hours. It is then cooled down to room temperature
24 and pulverized.

25
26 Comparative Example B: Triethoxy Octylsilane-coated TiO₂

27 Comparative Example A is repeated employing the same quantity of triethoxy
28 octylsilane in place of isopropyl titanium triisostearate. The coated powders obtained

1 from Comparative Examples A and B are used for comparison in tests such as those
2 described hereinbelow.

3
4 Comparative Examples C-D: Coated Red Iron Oxide

5 Comparative Examples A and B are repeated employing the same quantity of red iron
6 oxide from Sun Chemical Corporation in place of the titanium dioxide powder to yield
7 ITT-coated red iron oxide (Comparative Example C) and triethoxy octylsilane-coated
8 red iron oxide (Comparative Example D). The resultant coated powders are used for
9 comparison in tests such as those described hereinbelow.

10
11 Example 1: Hybrid Coating of TiO₂

12 98 g of titanium dioxide powder, product code X200 from Kemira Corporation, are
13 added to a blender. 5.9 g of a 34% wt/wt solution of a hybrid coating mixture (about
14 2% by weight of the coated product) comprising equal parts of isopropyl titanium
15 triisostearate and triethoxy octylsilane, referenced "the hybrid coating mixture"
16 hereinafter, are sprayed on the titanium dioxide powder under agitation. The mixture
17 is thoroughly blended, transferred to a tray and dried at 110 °C for 4 hours. It is then
18 cooled down to room temperature and pulverized to provide hybrid titanate-silicone-
19 coated titanium dioxide powder of a desired particle size.

20
21 Example 2: Hybrid Coating of Red Iron Oxide

22 Example 1 is repeated using 98 g of red iron oxide powder from Sun Chemical
23 Corporation in place of the titanium dioxide powder to yield titanate-silicone- coated
24 red iron oxide powder.

25
26 Example 3: Hybrid Coating of Yellow Iron Oxide and Black Iron Oxide

27 Example 1 is repeated using 98 g of yellow iron oxide powder or black iron oxide
28 powder in place of the titanium dioxide powder to yield titanate-silicone-coated
29 yellow or black iron oxide powder.

30
31 Example 4: Hybrid Coating of Barium Lake

32 Example 1 is repeated using 95 g of K 7096 D&C Red 6 barium lake from LCW in place
33 of the titanium dioxide powder to yield titanate-silicone-coated barium lake powder.

34
35 Example 5: Hybrid Coating of Mica

36 Example 1 is repeated using a similar quantity of mica in place of the titanium dioxide
37 powder to yield titanate-silicone-coated mica powder.

38
39 Example 6: Hybrid Coating of Silica

Example 1 is repeated using a similar quantity of silica in place of the titanium dioxide powder to yield titanate-silicone-coated silica powder.

Each of the powders coated with hybrid material produced by the methods of Examples 1-6 shows good water repellency, has a smooth feel and good adhesion to the skin.. After mixing and shaking with water, each hybrid-coated powder floats well and the water soon becomes a similar.

The properties of the hybrid coated powder products obtainable by the methods of Examples 1-5 can be determined by various tests, as known to those skilled in the art, some of which are described below:

Test 1: Hydrophobicity

In a quick and simple test to determine hydrophobicity, 1 g of pigment powder is shaken vigorously 10 times in a glass container in 50 ml of water. The sample is allowed to stand for one minute and the clarity of the water is observed. Results obtainable are shown in Table 1 below.

Table 1: Hydrophobicity			
	Example A	Example B	Example 1
Water phase	Cloudy	Clear	Clear

The treatment of titanium dioxide pursuant to Comparative Example A, employing isopropyl titanium triisostearate, provides a product which is significantly less hydrophobic than is obtainable with Comparative Example B, employing a silane, triethoxy octylsilane. Example 1, wherein titanium dioxide is coated with a hybrid composition according to the present invention, exhibits comparable hydrophobicity to the silane treatment of Comparative Example B being also significantly better than isopropyl titanium triisostearate, Comparative Example A.

Test 2: pH Stability

0.5 g of fine coated pigment powder are carefully deposited onto the surface of 50 g of distilled water having the indicated pH in a 100 ml beaker. The time when the pigment powder starts to break the surface and sink into the water is observed. Results obtainable are shown in Table 2 below.

1

Table 2: pH Stability			
	Time when particles begin to sink		
pH	Example A	Example B	Example 1
pH4	3 hr. 20 min.	> 2 weeks	> 2 weeks
pH5	> 3 days		
pH6	> 3 days		
pH7	> 5 days		
pH8	> 7 days		
pH9	> 7 days		

2

3 The pigment treated pursuant to Comparative Example A, isopropyl titanium
4 triisostearate coated, shows loss of hydrophobicity at all tested alkaline, neutral and
5 acid pHs after 7 days, i.e. before 8 days. In the case of acid pHs the loss becomes
6 apparent after about 3 days. In contrast, both the silane-coated product of
7 Comparative Example B and the hybrid-coated product of Example 1 of the
8 invention are stable for more than two weeks at all pHs in the test. Both products
9 have a hydrophobicity which is significantly more resistant to acid pHs than is that
10 of pigment coated with isopropyl titanium triisostearate. Thus, the hybrid coating
11 of Example 1 displays excellent stability over a wide pH range.

12

13 Test 3: Dispersibility in Hydrophobic Fluids

14 Various proportions of pigment powder, as shown in Table 3 below, are blended
15 into two different hydrophobic fluids, namely mineral oil and a cyclomethicone
16 product, for example GE Silicones product number SF1528 which is described as a
17 water-in-oil silicone emulsifier comprising a 10% silicone polyether copolymer
18 dispersed in cyclopentasiloxane (a cyclomethicone). The viscosities of the resultant
19 dispersions are determined by known methods and results obtainable are shown in
20 Table 3 below from which it may be seen that, surprisingly the hybrid coated
21 pigments of the invention have good dispersibility in both oils and silicone fluids.

22

Table 3: Dispersibility in Hydrophobic Fluids				
Pigment Tested	In Mineral Oil		In Cyclomethicone	
	Solids%	Viscosity	Solids%	Viscosity
<u>Titanium dioxide</u> Uncoated	40	346,000	73	N/A
Comparative Example A: ITT*-coated	80	108,400	75	1,316,000
Comparative Example B: Silane-coated	80	698,000	75	505,000
Invention Example 1: Hybrid-coated	80	286,000	75	761,000

<u>Red Iron Oxide (Cosmetic russet)</u>				
Uncoated	50	N/A	60	1,312,000
Comparative Example C: ITT*-coated	75	121,200	73	824,000
Comparative Example D: Silane-coated	75	627,000	73	292,000
Invention Example 2: Hybrid-coated	75	126,400	73	488,000
*ITT = isopropyl titanium triisostearate				

1

2 The uncoated pigments are difficult to disperse in either liquid. Even at the lower
3 solids loadings indicated the resultant dispersion is either very viscous or the
4 viscosity cannot readily be measured. The inventive hybrid coating, Examples 1
5 and 2, improves the dispersibility of both titanium dioxide and red iron oxide
6 significantly over the uncoated pigment powders.

7

8 Furthermore, the hybrid coated pigment powders of the invention exhibit
9 significant lipophilicity as shown by a marked improvement in the dispersibility, of
10 both pigment powders in oils, e.g. mineral oil, as is indicated by the relatively lower
11 viscosities in such a medium, that are shown in Table 3. In the case of red iron
12 oxide, the hybrid coating of Example 2 is almost as effective as the isopropyl
13 titanium triisostearate coating of Comparative Example C.

14

15 In contrast, the silane-coated pigments of Comparative Examples B and D which
16 disperse well in the cyclomethicone fluid, yield highly viscous dispersions in
17 mineral oil, indicating poor lipophilicity.

18

19 Results for the dispersibility of the pigments in cyclomethicone show that the
20 hybrid-coated pigment of Examples 1 and 2 is has good dispersibility in silicone
21 fluids such as the above-described cyclomethicone material, showing a substantial
22 reduction in viscosity as compared with the isopropyl titanium triisostearate treated
23 pigments of Comparative Examples A and C or the uncoated pigments. or
24 compatible provides a as effectively as silane coating.

25

Test C shows that the inventive hybrid coating can provide a combination of desirable properties which are exhibited individually by isopropyl titanium triisostearate and silane coatings, namely both good lipophilicity and good silicone fluid dispersibility.

Test 4: Stability during Grinding

To determine the stability of the pigment coating during grinding, the coated pigments are dispersed in a suitable cosmetic pigment emulsifier using a mixer and are ground in a mill. Employing an emulsifier supplied by Goldschmidt Chemical Corp., Hopewell, VA under the trademark ABIL® WE 09, the results described in Table 4, below are obtainable. The ABIL® WE 09 emulsifier is described as comprising a mixture of (polyglyceryl-4 isostearate, cetyl dimethicone copolyol and hexyl laurate.

Table 4: Grinding Stability		
Dispersion Formula		Odor
70 parts ITT-coated TiO ₂ (Comparative Example A)	30 parts emulsifier	Slight waxy odor
70 parts hybrid-coated TiO ₂ (Invention Example 1)	30 parts emulsifier	Little, if any odor.

The hybrid coating of Example 1 has a dispersibility in the emulsifier, for example Abil® WE 09 emulsifier, which is comparable with that of the isopropyl titanium triisostearate coating, yet generates little or no odor, an important consideration for the aesthetics of finished consumer products.

Comparative Example E Methicone-coated TiO₂

96 g of ultrafine titanium dioxide powder, product code A0189 from ISK Co., Japan, average particle size no greater than 100nm, are added to a blender. 11.76 g of a solution of methicone (34% wt/wt) product code KF-9901 from Shin-Etsu Chemical Co. Ltd. in isopar C are sprayed on the powder under agitation. The mixture is well blended, transferred to a tray and dried at 110 °C for 4 hours. It is then cooled down to room temperature and pulverized to a desired particle size. The methicone-coated titanium dioxide powder obtained shows poor hydrophobicity. After mixing and shaking with water, the powder disperses into water and the water remains cloudy indicating poor hydrophobicity.

Comparative Example F Methicone-coated ZnO

Comparative Example E is repeated with the difference that a similar quantity of ultrafine zinc oxide powder, average particle size no greater than 100 nm is employed in place of the titanium dioxide powder. A similar result is obtained.

Example 7: Hybrid Coating of TiO₂ Employing Methicone

Comparative Example E is repeated except that 11.76 g of a solution of a mixture of ITT (17% wt/wt based on the solution) and methicone (17% wt/wt based on the solution) in isopar C is employed in place of the solution of methicone. The hybrid titanate-methicone-coated titanium dioxide powder obtained shows excellent hydrophobicity. After mixing and shaking with water, the powder floats well and the water soon becomes clear, indicating excellent hydrophobicity.

Comparing Example 7 with Comparative Example E shows that coating of ultrafine titanium dioxide with the inventive hybrid titanate-methicone composition yields a product with surprisingly superior hydrophobicity to that of a conventionally treated methicone coated product. In addition, while the invention is not limited by any particular theory, it is hypothesized that use of an organotitanate, or other organometallate pursuant to the invention may result in more complete reaction of the methicone -Si-H groups, relieving the problem of spontaneous hydrogen generation in storage to which methicone-containing products are subject. In addition, methicone-induced color shift during storage is expected to be inhibited.

Example 8: Hybrid Coating of ZnO Employing Methicone

Example 7 is repeated with the difference that a similar quantity of ultrafine zinc oxide powder, average particle size no greater than 100 nm, is employed in place of the titanium dioxide powder. A similar result is obtained.

Example 9: Oil-in-Water Liquid Makeup

The following ingredients are employed in the proportions indicated to prepare an oil-in-water liquid makeup:

Part A	%
Lanolin Alcohol (and) Mineral Oil	11.50
Cetyl esters	3.20
Stearic Acid	3.50
Glyceryl Monostearate	1.80
Talc	2.00
Titanium dioxide (w/hybrid coating)	4.00
Yellow iron oxide (w/hybrid coating)	1.00
Red iron oxide (w/hybrid coating)	0.40
Black iron oxide (w/hybrid coating)	0.15
Part B	
Propylene glycol	12.00
Triethanolamine	1.00
PE 20 Sorbitan Monolaurate	0.65
Magnesium Aluminum Silicate	1.00
Carboxymethyl Cellulose	0.30
Deionized Water	57.20
Preservatives and Fragrance	QS

The titanium dioxide and iron oxide pigments are provided with hybrid coatings pursuant to the invention, for example as described in Examples 1-3. The ingredients of Part A are combined, in the order shown, while thoroughly mixing each component until homogenous before adding the next ingredient. The mixture is heated to 60°C. The ingredients of Part B are combined in a separate vessel. The mixture of Part B ingredients is slowly added to the Part A mixture with good mixing and the product is poured into suitable containers. A high quality product is obtained.

Example 10: Liquid Compact Foundation (Hot pour)

The following ingredients are employed in the proportions indicated to prepare a hot pour liquid compact foundation:

Part A	%
Titanium dioxide (w/hybrid coating)	26.76
Red iron oxide (w/hybrid coating)	0.54
Yellow iron oxide (w/hybrid coating)	0.54
Black iron oxide (w/hybrid coating)	0.16
Mica (w/hybrid coating)	10.00
Silica (spherical) (w/hybrid coating)	2.00
Part B	
Squalene	10.00
Dimethicone (5 cst)	17.00
Octyl hydroxystearate	7.00
Polyglyceryl-3 diisostearate	3.00
Microcrystalline wax	7.00
Octyl palmitate	7.00
Carnauba wax	1.00
Part C	
Nylon -12	8.00

Each of the pigment materials in Part A is provided with a hybrid coating pursuant to the invention, for example as described in Examples 1-5. The ingredients of Part A are micronized until the color is fully developed. The ingredients of Part B are heated, with stirring, to about 90-93 °C (195 - 200 °F). Continue to stir for ½ hour. Add Part A to Part B and mix until homogeneous. Cool to about 82 °C (180°F). The Part C ingredient and mixing is continued until the mixture is homogeneous and is then poured into pans at about 74-77 °C (165-170) °F. A high quality product is obtained.

Example 11: Lipstick

The following ingredients are employed in the proportions indicated to prepare a hot pour liquid compact foundation:

Ingredient	%
-------------------	----------

Candelilla Wax	6.00
Carnauba Wax	3.00
Ozokerite	4.00
Paraffin Wax	2.00
Yellow Beeswax	6.00
Lanolin Alcohol	6.00
Oleyl Alcohol,	10.00
BHA	0.20
Castor Oil	43.25
D&C Red No. 6 Barium Lake (w/hybrid coating)	2.50
D&C Red No. 7 Calcium Lake (w/hybrid coating)	2.50
Iron Oxides (w/hybrid coating)	1.00
FD&C Blue No. 1	0.80
Perfume	0.75
Titanium Dioxide (and) Mica (w/hybrid coating)	10.00

Each of the pigment materials is provided with a hybrid coating pursuant to the invention, for example as described in Examples 1-8. Castor oil is placed in the main mixer and heated to 80 °C using a steam pan. The coated lakes, coated iron oxides and the dyes are slowly mixed into the castor oil using a Lightnin' mixer under high speed for 30-60 minutes. The candelilla wax, carnauba wax, beeswax, ozokerite paraffin wax oleyl alcohol and lanolin alcohol are all preheated and melted together at 80 -85 °C using a steam pan and added to the castor oil, pigment and dye mixture. Mixing is continued throughout the addition of these ingredients.

The perfume is then added and mixing is continued until the mixture is homogeneous. The hybrid coated titanium dioxide and mica, pigments providing pearlescence, are then added and mixing continues until the product is uniform. The lipstick is then cooled and shaped in conventional manner. A high quality product with excellent coverage is obtained.

The powder coating agents, methods and products of the invention enable a wide range of cosmetics powders to be coated with the same treatment and provide a broad spectrum of dispersibility properties enabling the coated powders to be utilized in a diversity of media including aqueous, lipid or oily media and silicone fluids. A particular benefit of the invention is that a diversity of different powder ingredients in a multiphase cosmetic formulation may receive the same hydrophobizing treatment and may in some cases be mixed together and coated in a single process.

1 In summary, the hybrid coating of the invention can provide, in preferred
2 embodiments, in a single coating, many of the benefits that are known to be
3 obtainable separately with either an ITT coating or a silane coating. The inventive
4 hybrid coatings can improve the dispersibility of pigments and other powders in
5 oils nearly as effectively as does an ITT coating and in cyclomethicone nearly as
6 effectively as does a silane coating.

7

8 INDUSTRIAL APPLICABILITY

9 The present invention is particularly suitable for application in the cosmetics
10 industry providing novel and improved coated powder ingredients, processes and
11 consumer products such as makeups, foundations, lipsticks and the like. In
12 addition, the novel hybrid coated powders of the invention, coating compositions
13 and processes and end product formulations containing the coated powders may be
14 useful in other industries, for example, in the paints and coatings industries and
15 the plastics, rubber, adhesives, tile and other industries where the novel properties
16 of the inventive materials and processes may be advantageous.

17

18 Other possible fields of application will be known or apparent to those skilled in the
19 art from the disclosures herein. It will also be understood that the particular
20 materials selected for such applications in other industries may not be required to
21 meet accepted criteria for cosmetic compatibility, enabling the skilled worker to
22 choose from among a broad range of possible ingredients the particular ingredients
23 to use to practice the invention.

24

25 Disclosures Incorporated

26 The entire disclosure of each and every United States patent and patent application,
27 each foreign and international patent publication, of each other publication and of
28 each unpublished patent application that is referenced in this specification or

1 elsewhere in this patent application, is hereby incorporated herein, in its entirety,
2 by the respective specific reference that has been made thereto.

3

4 While illustrative embodiments of the invention have been described above, it is, of
5 course, understood that many and various modifications will be apparent to those
6 of ordinary skill in the relevant art, or may become apparent as the art develops.
7 Such modifications are contemplated as being within the spirit and scope of the
8 invention or inventions disclosed in this specification.
